1. **Diagnosing COPD**

COPD is characterised by persistent respiratory symptoms and airflow limitation.

The common respiratory symptoms include breathlessness, cough and/or sputum production.

COPD may be punctuated by periods of worsening of respiratory symptoms called exacerbations.

In most patients, COPD is associated with significant concomitant chronic diseases, which increase its morbidity and mortality.

**Consider any patient over the age of 35 with symptoms of (in varying proportions):**
- breathlessness
- chronic cough
- regular sputum production
- history of exposure to risk factors, especially cigarette smoking
- repeated chest infections.

**Post bronchodilator spirometry must confirm diagnosis.**

2. **Risk Factors**

**Exposure:**
- Tobacco smoking
- Occupational dusts or chemicals
- Indoor and outdoor air pollution/particulates
- Cannabis smoking
- Respiratory infections in childhood.

**Host:**
- Alpha-1- antitrypsin deficiency
- Lower socio-economic status
- Asthma.

3. **Diagnostic Tests**

All new diagnoses of COPD require spirometry.

A post bronchodilator FEV1/FVC ratio < 0.7 (Note: spirometers often express this as 70%) indicates the presence of chronic airflow limitation and is a diagnostic criterion for COPD.

Reversibility testing is not necessary for the diagnosis, or to plan treatment.

Consider asthma if the FEV1 returns to normal or results in an increase of >400mls post-bronchodilator.

Individuals may have both asthma and COPD (The Asthma COPD overlap syndrome has features of both asthma and COPD).

In trying to distinguish between COPD and asthma, a careful history of childhood symptoms such as variable wheeze, or atopy (eczema, rhinorrhea, hayfever etc.) and nocturnal symptoms is essential.
Assessment

The goals of assessment in COPD are to determine:

- the level of airflow limitation
- the impact of disease on the patient’s health status
- the risk of exacerbations and hospital admissions.

No single measure provides an adequate assessment of the severity of the disease in an individual patient. Severity assessment has implications for therapy and relates to prognosis.

The severity of airflow obstruction is defined as follows:

<table>
<thead>
<tr>
<th>Post-bronchodilator FEV₁</th>
<th>≥80%predicted</th>
<th>50-79%predicted</th>
<th>30-49%predicted</th>
<th>&lt;30%predicted</th>
</tr>
</thead>
<tbody>
<tr>
<td>FEV₁/VC Ratio</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ratio &lt;0.7 (70%)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Patients with a post FEV₁/VC ratio < 0.7 may have mild COPD but in the elderly, this can lead to an over-diagnosis of COPD.

The FEV₁ poorly reflects the degree of disability in COPD.

A more comprehensive assessment of severity includes assessing the degree of airflow obstruction and the known prognostic factors as follows:

- Symptoms (modified MRC scale or CAT)
- Risk of exacerbations
- Co-morbidities
- BMI
- Oxygen saturation (SaO₂)
- Cor pulmonale.

PLEASE TICK IN THE BOX THAT APPLIES TO YOU (ONE BOX ONLY) (Grades 0-4)

mMRC Grade 0. I only get breathless with strenuous exercise.

mMRC Grade 1. I get short of breath when hurrying on the level or walking up a slight hill.

mMRC Grade 2. I walk slower than people of the same age on the level because of breathlessness, or I have to stop for breath when walking on my own pace on the level.

mMRC Grade 3. I stop for breath after walking about 100 meters or after a few minutes on the level.

mMRC Grade 4. I am too breathless to leave the house or I am breathless when dressing or undressing.

Modified MRC (mMRC) dyspnoea score is a simple tool to assess degree of breathlessness in COPD.
The COPD assessment test (CAT) also provides a comprehensive assessment of symptoms.

4. **Assess Risk of Exacerbations**

COPD exacerbations are defined as an acute worsening of respiratory symptoms that result in additional therapy. Classified as:

- Mild (treated with short acting bronchodilators [SABDs] only)
- Moderate (treated with SABDs plus antibiotics and/or oral corticosteroids)
- Severe (patient requires hospitalization or visits the emergency room)
- Severe exacerbations may also be associated with acute respiratory failure.

5. **Assess Co-morbidities**

COPD is associated with all of the conditions listed below. They have many risk factors in common. Consider and treat these conditions. Untreated co-morbidities lead to poor clinical outcomes:

- cardiovascular disease
- depression/anxiety
- osteoporosis
- carcinoma of the lung
• weight loss and skeletal muscle dysfunction including muscle wasting
• diabetes

6. **ABCD Assessment Tool**

![ABCD Assessment Tool Diagram]

**Spirometrically confirmed diagnosis** → **Assessment of airflow limitation** → **Assessment of symptoms/risk of exacerbations**

<table>
<thead>
<tr>
<th>FEV₁ (% of predicted)</th>
<th>GOLD 1</th>
<th>≥80</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>GOLD 2</td>
<td>50–79</td>
</tr>
<tr>
<td></td>
<td>GOLD 3</td>
<td>30–49</td>
</tr>
<tr>
<td></td>
<td>GOLD 4</td>
<td>&lt;30</td>
</tr>
</tbody>
</table>

**Exacerbation history**

- ≥2 or ≥1 leading to hospital admission
- 0 or 1 (not leading to hospital admission)

**Symptoms**

- mMRC 0–1
  - CAT <10
- mMRC ≥2
  - CAT ≥10

---

**Examples**

Consider two patients:

- Both patients with FEV₁ < 30% of predicted
- Both with CAT scores of 18
- But, one with 0 exacerbations in the past year and the other with 3 exacerbations in the past year.
- Both would have been labelled GOLD D in the prior classification scheme.

With the new proposed scheme, the subject with 3 exacerbations in the past year would be labelled GOLD grade 4, group D.

- The other patient, who had no exacerbations, would be classified as GOLD grade 4, group B.

7. **Chest X-ray**

A chest x-ray is not essential to establish the diagnosis of COPD however is often helpful when considering alternative diagnoses.

A chest x-ray is part of the post-diagnosis assessment, especially with patients who smoke.

Clinicians should have a low threshold for requesting a chest x-ray in any patient who smokes and has respiratory symptoms.

A chest x-ray must be done if:

- patient is not responding to treatment
- there is a possibility of a new or alternative diagnosis
- the patient’s condition is worsening.

8. **Other Investigations**

<table>
<thead>
<tr>
<th>Investigation</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serial domiciliary peak flow measurements</td>
<td>to exclude asthma if diagnostic doubt remains</td>
</tr>
<tr>
<td>Alpha-1 antitrypsin</td>
<td>if early onset (&lt; 45 years), minimal smoking history or family history</td>
</tr>
<tr>
<td>Transfer factor for carbon monoxide (TLCO)</td>
<td>to investigate symptoms disproportionate to spirometric impairment</td>
</tr>
<tr>
<td>CT scan of the thorax</td>
<td>to investigate symptoms disproportionate to spirometric impairment</td>
</tr>
<tr>
<td></td>
<td>to investigate abnormalities on CXR, rule out associated bronchiectasis</td>
</tr>
<tr>
<td></td>
<td>to assess suitability for surgery/ endobronchial valves</td>
</tr>
<tr>
<td>ECG</td>
<td>to assess cardiac status if features of cor pulmonale</td>
</tr>
<tr>
<td>Echocardiogram</td>
<td>to assess cardiac status if features of cor pulmonale</td>
</tr>
<tr>
<td>Pulse oximetry</td>
<td>to assess need for oxygen therapy</td>
</tr>
<tr>
<td></td>
<td>if cyanosis or cor pulmonale present or if FEV1 &lt; 50% predicted</td>
</tr>
<tr>
<td>Sputum culture</td>
<td>to identify organisms if sputum is persistently present and purulent or during an exacerbation</td>
</tr>
</tbody>
</table>

9. **Treatment of COPD**

9.1 **Treatment aims to:**
- Reduce risk factors
- Relieve symptoms
- Improve exercise tolerance
- Improve health status
- Prevent and treat complications
- Prevent and treat exacerbations
- Reduce the effects of co-morbidities
- Reduce mortality
- Maximize the patients and carers understanding of the disease.

**Reduce risk factors by:**
- Stop smoking (this reduces the rate of progression of the disease)
- Flu vaccination
- Pneumococcal vaccination
- Pulmonary rehabilitation.

**Measure treatment effectiveness by:**
- Improvement in symptoms
- Increase in activities of daily living
- Improvement in exercise tolerance.
Questions to assess response to therapy:
- Has your treatment made any difference to you?
- Is your breathing any easier?
- Can you do things now that you could not do before?
- Can you do things now faster than before?
- Can you do the same things now but with less breathlessness?

9.2 Inhaler therapy for stable disease (also see appendix for colored flow chart):

The assessment of COPD takes into account many factors that define the severity of COPD. This in turn helps with decisions on the most appropriate therapy options.

There have been many recent changes in the drugs and delivery systems for inhalers, used in COPD. The Lothian Joint Formulary (LJF) revised its advice for drugs to use for COPD in 2018.

The following drugs are recommended by the LJF for use in COPD (see Appendix 1 for help with this):

<table>
<thead>
<tr>
<th>SABA</th>
<th>Salbutamol or Terbutaline prn</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAMA</td>
<td>Ipratropium Bromide (1-2 puffs four times daily)</td>
</tr>
<tr>
<td>LAMA</td>
<td>Umeclidinium Bromide (1 puff once daily)</td>
</tr>
<tr>
<td></td>
<td>Tiotropium Respimat (2 puffs once daily)</td>
</tr>
<tr>
<td></td>
<td>Glycopyrronium (Seebri Breezehaler) (1 capsule once daily)</td>
</tr>
<tr>
<td>LABA/LAMA</td>
<td>Anoro Ellipta (umeclidinium with vilanterol) (1 puff once daily)</td>
</tr>
<tr>
<td></td>
<td>Spiolto Respimat (Tiotropium with olodaterol) (2 puffs once daily)</td>
</tr>
<tr>
<td></td>
<td>Ultibro Breezehaler (Glycopyrronium with indacaterol) (1 capsule once a day)</td>
</tr>
<tr>
<td>ICS/LABA</td>
<td>Fostair (100/6) (beclomethasone and formoterol) (2 puffs twice daily)</td>
</tr>
<tr>
<td></td>
<td>Relvar (92/22) (Fluticasone and vilanterol) (1 puff once daily)</td>
</tr>
</tbody>
</table>

*SABA = Short-Acting Beta Agonist/SAMA = Short-Acting Muscarinic Antagonist/LABA = Long-Acting Beta Agonist/LAMA = Long-Acting Muscarinic Antagonist/ICS = Inhaled Corticosteroid.

ICS/LABA/LAMA triple therapy devise is in the formulary now too: Trimbow MDI and Trelegy Ellipta, follow GOLD guidelines to choose appropriate patients for this (see Appendix 1).

It is important to note that in Scotland the Scottish Medicines Consortium (SMC) has not accepted the use of any LABA + ICS combination inhaler where the FEV1>50%. Individual clinicians should take account of SMC’s advice when exercising their clinical judgment.

Low dose theophylline may exert a small bronchodilator effect in stable COPD and that is associated with modest symptomatic benefits, no role of increasing the dosage to attain therapeutic levels.

Long-term azithromycin therapy reduces exacerbations over one year in patients with severe COPD (consult a specialist prior to starting this).

Long-term use of oral glucocorticoids has numerous side effects without any evidence of benefit in COPD.
9.3 Pharmacologic treatment by GOLD grade: Highlighted boxes and arrows indicate preferred treatment

9.4 Frequently Asked Questions

Can the FEV₁ be used to assess the response to treatment?
While the FEV₁ measurement is critical to establishing COPD diagnosis, it is seldom useful when assessing the response to therapy

Judge clinical response by improvement of symptoms, exercise tolerance, activities of daily living

The mMRC scale of breathlessness score may show improvements in breathlessness. However, meaningful improvements in symptoms can occur without any change in this score and thus it is not used to assess the response to treatment.
What is the place of theophylline?
This may be given for a trial period after treatment with long-acting bronchodilator/ICS combination inhaler therapy has failed or symptoms persist.

Monitor response and continue treatment only if the symptoms improve. Monitor plasma levels and be aware that many drugs can modify theophylline metabolism, including smoking.

Should oral corticosteroids be used for maintenance treatment?
In COPD, it is not recommended that they be used for maintenance.

Should inhaled corticosteroids be used alone in patients with COPD?
They do not have a license for COPD and should not be prescribed alone.

What benefit can combination inhalers (Inhaled corticosteroids / long acting beta agonists) provide patients with COPD?
Combination inhalers can:

- reduce breathlessness
- improve lung function
- reduce exacerbations
- improve the quality of life.
- they should be used for patients with severe airways obstruction (FEV1<50% of predicted, see treatment chart) and repeated exacerbations
- the patient should be checked after a few months and the clinical benefit of the inhaler should be reviewed. The inhaler should be stopped if no clinical benefit is achieved.
- (see treatment chart on page 9)

However, inhaled corticosteroids may increase the incidence of pneumonia especially in the elderly.

The cost efficiency of combined inhalers should be considered.

Types of inhaler differ in price and new preparations now have varied dosage regimes.

Should mucolytics be used?
The Lothian Joint Formulary Committee has not approved their use and the evidence is poor.

If prescribed they should be reassessed after one month for any benefits.

10. Delivery Systems

The correct delivery system is as important as the drug used

INHALERS
Be sure to:

- teach the technique and re-check (focus on inspiratory flow and hand to breath coordination)
- be familiar with different types of inhalers
- inhalers if a patient is having trouble coping with a certain type
- encourage the use of spacer devices when needed.
NEBULISERS

- Nebuliser assessments trials should be done by secondary care respiratory physicians (this gives an added benefit to the patient of having the nebuliser maintained)
- Nebulisers are only considered in patients with severe airways obstruction (FEV1 < 50 predicted) if the patient has excessive or distressing shortness of breath despite maximum therapy
- Nebulised therapy should not continue to be prescribed without confirming improvement in one or more of the following:
  - a reduction in symptoms and/or
  - an increase in activities of daily living or exercise capacity.

11. Oxygen Therapy

Short-burst oxygen therapy (SBOT)
There is no good evidence to support the use of short burst oxygen therapy.

Long-term oxygen therapy (LTOT)

- LTOT can prolong life. It is indicated in patients with hypoxaemia (PaO₂ < 7.3 kPa) when in a stable condition;
- or PaO₂ between 7.3 kPa and 8.0 kPa if there is evidence of pulmonary hypertension, peripheral edema suggesting cor pulmonale, or polycythemia (hematocrit > 55%).

Secondary care assessment is required for the provision of long-term oxygen therapy.

Consider long-term oxygen therapy in patients with:
- severe airflow obstruction
- cyanosis
- polycythemia
- raised JVP or peripheral oedema
- pulmonary hypertension
- O₂ saturation of < 92% while breathing air.

Patients who continue to smoke will rarely be considered for long-term oxygen therapy.

Consider ambulatory oxygen therapy in mobile patients on long-term oxygen therapy.

Oxygen therapy:
- Can only be prescribed by the Respiratory consultants or the respiratory Nurse specialists in each acute hospital
- Can only be prescribed after careful assessment applying the above criteria.
- All community oxygen in Scotland is supplied by Dolby Vivisol.

12. Pulmonary Rehabilitation

Evidence shows that pulmonary rehabilitation benefits all patients with COPD, particularly those with severe to very severe COPD or an MRC breathlessness score of three or more.

Patients with moderate COPD are usually still active and have fewer symptoms.

All patients with repeated exacerbations or who are admitted to hospital with an exacerbation should be fast tracked for pulmonary rehabilitation.
Pulmonary rehabilitation:
- Improves exercise tolerance
- Improves the quality of life
- Reduces symptoms
- Reduces the number of exacerbations
- Reduces hospital admissions
- Is available in all CHPs (in Edinburgh CHP, home-based rehabilitation is available).

For contact information see section 18 (page 14)

### 13. Exacerbations

**Symptoms:**
- Increase in shortness of breath
- Increase in cough
- Increase in sputum volume and purulence
- Decreased exercise tolerance
- Drowsiness.

Consider prescribing a long-acting β2 agonist/steroid combination inhaler if the FEV1 is < 50%.

Consider and select patients who may benefit from having antibiotics and steroids at home.

Patients should be encouraged to start treatment early in an exacerbation. Use the Lothian self-management plan (see Appendix 2)

If the patient is drowsy they should always be admitted unless palliative care is considered.

Patients in the community should have oximetry available to help assess exacerbation severity.

**Criteria for discharge:**
- Patient and carer understand use of inhalers
- Home care arrangements in place, for example oxygen, supported home care and specialist nurse follow-up
- Family, patient, nurses, AHP, community health partnership (CHP) staff and medical staff confident that the patient will cope
- Follow up at respiratory clinic or by specialist nurse within 4 to 6 weeks in community respiratory team services (see CHP variations)
- COPD self-management plan.

### 14. Referral for Consultant Opinion

Consider referral if:
- diagnosis is unclear
- patient has very severe COPD (FEV1 < 30% of predicted)
- cor pulmonale (fluid retention or peripheral oedema)
- increasing shortness of breath
• haemoptysis
• rapidly decreasing FEV1
• for assessment for O2 therapy if oxygen saturation (92% or less) while breathing air
• for consideration for interventional bronchoscopic or surgical treatment
  (endobronchial values, bullectomy, lung volume reduction surgery, lung transplantation)
• patient is less than 40 years old
• symptoms are disproportionate to pulmonary function
• patient has frequent infections/exacerbations
• for assessment for nebuliser.

Please note there are now community respiratory teams focusing on COPD management, based in Edinburgh City (7 day service) and Midlothian (Monday-Friday) as well. These teams focus mainly on exacerbation management and hospital admission prevention along with facilitated discharges from secondary care.

15. Palliative Care

Many patients will reach a stage in their illness where palliative care should be considered and will be of benefit. Making an exact prognosis is difficult in COPD.

The ‘surprise’ question may help - “would you be surprised if this patient died in the next year?”

If the answer is “no” the patient may be in the palliative phase of their illness. Some patients may express this by saying “hospital admissions make me feel worse rather than better.”

In the palliative care stage the focus should change. Discuss interventions with the patient to maximise their understanding and decision-making.

Things to consider:
• Share understanding with colleagues (palliative care register)
• Concentrate on symptom reduction
• Maximise the patient’s understanding of their illness
• Consider an anticipatory care plan for palliative care (symptoms, place of care, DNAR, essential treatments)
• Notify out of hours for DNAR status and special notes
• Maximise support for family
• Opioids, benzodiazepines, and tricyclic antidepressants should be used when appropriate for breathlessness in patients with end-stage COPD unresponsive to other medical therapy (see Palliative Care guidelines).

16. Travelling with COPD

Patients travelling with long-term oxygen therapy need advanced planning (one month before departure):
• All community oxygen in Scotland is supplied by Dolby Vivisol
• All patients in Scotland can have oxygen delivered to their holiday destination with advanced planning
• All patients travelling within the UK can have oxygen supplied with advanced planning
• All requests should be made by the patient to Dolby Vivisol, by telephoning the
number attached to all oxygen equipment
• The NHS does not supply oxygen when travelling outside the UK
• Air travel involves exposure to a relatively hypoxic environment during a flight. The great majority of patients can and do fly without difficulty.

Guidelines indicate:
• Patients with moderate or severe COPD and resting saturation over 95% are safe to fly without oxygen
• All patients on long-term oxygen therapy plus oxygen saturation below 92% on air should arrange in advance for in-flight oxygen
• Patients with significant COPD and oxygen saturation between 92% and 95% may benefit from a referral for a fitness-to-fly test. During a flight the degree of desaturation in this group is unpredictable (refer to respiratory outpatient department).

20. Protocol for Management of COPD Exacerbation in Primary Care

Chronic obstructive pulmonary disease (COPD) can be punctuated by exacerbations (a change in the patient's baseline breathlessness, cough, and/or sputum volume or purulence that is beyond normal day-to-day variations, is acute in onset, and may warrant a change in regular medication in a patient with underlying COPD).

They are classified as:
- Mild (treated with short acting bronchodilators only, SABDs)
- Moderate (treated with SABDs plus antibiotics and/or oral corticosteroids) or
- Severe (patient requires hospitalization or visits the emergency room). Severe exacerbations may also be associated with acute respiratory failure.

Bronchodilators and corticosteroids are the mainstay of treatment of exacerbations. Antibiotics should be used for patients with an increase in breathlessness, volume of sputum and sputum purulence, or an increase in two of these symptoms if increased sputum purulence.

Many patients with an exacerbation of COPD can be managed successfully at home.

All acute exacerbations can also be assessed and cared for by:
<table>
<thead>
<tr>
<th>Edinburgh Community Respiratory Team (CRT)</th>
<th>07826 894 067</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>8am – 6pm (Monday to Friday)</td>
</tr>
<tr>
<td></td>
<td>8.30am – 4.30pm (Saturday &amp; Sunday)</td>
</tr>
<tr>
<td>Midlothian Community Respiratory Team (CRT)</td>
<td>0131 270 8890 and 07779 967 349</td>
</tr>
<tr>
<td></td>
<td>8.30am – 4.30pm (Monday to Friday)</td>
</tr>
<tr>
<td>West Lothian REACT (for patients over 75 years)</td>
<td>01506 524149</td>
</tr>
<tr>
<td></td>
<td>8.30am – 6pm (Monday to Friday)</td>
</tr>
</tbody>
</table>

These community based teams will help and advise or take over the care of patients. The CRT may enable treatment of exacerbations in the community thus preventing the need for hospital admission. The CRT has admitting rights.

LUCS and the CRT have direct telephone contact for advice from a respiratory consultant. Patients should be considered for direct admission to hospital if there is evidence of a severe exacerbation of COPD (oxygen saturations significantly below the patient’s normal measurement, or confusion) and for those who do not respond to initial treatment.

Decisions about management of a patient with an exacerbation of COPD will vary depending on the patient’s individual circumstances including the severity of their underlying disease, the presence of other medical conditions, and their social situation. The community teams can manage complex cases and so help support patient care at home.
Protocol for COPD Exacerbations in Primary Care

Patient attends GP practice or Out of Hours service
LUCS with exacerbation

Are there symptoms or signs of severe exacerbation?
History
Marked increase in severity of symptoms including:
- Breathlessness
- Cough or sputum
- New limitation of daily activities
Examination
Onset of new physical signs
- Oxygen saturates below patient's normal value
- Central cyanosis
- Peripheral oedema
- Reduced consciousness or confusion

Are there other factors that give cause for concern?
- Three or more exacerbations in past year
- Previous hospital admission requiring ventilation e.g. NIV
- Significant co-morbidities and/or diagnostic uncertainty
- Poor socioeconomic conditions (e.g. not coping at home)
- No improvement despite optimal therapy

CRT Edinburgh CHP
REACT West Lothian CHP

Pulmonary Rehabilitation

GP management of the patient at home or referral to CRT (Edinburgh) or REACT (West Lothian) if >70
- Maximise bronchodilator therapy (e.g. via spacer device/neti nebuliser)
- Corticosteroid if no contraindications (30mg prednisolone) for 7 days

Antibiotics if increased purulent sputum—amoxicillin 500mg 3 times a day for 5 days:

If penicillin allergy, Doxycycline 200mg, day 1 then 100mg for 4 days

Consider emergency admission to hospital

Advise patient about actions to take if deterioration in symptoms (including contact with NH324)
Monitor patient regularly, and review markers of severity

**NOTE:** Fostair\(^{®}\) 200/6 and Relvar\(^{®}\) 184/22 are NOT licensed for use in COPD

Please ensure any inhaler containing an Antimuscarinic (LAMA, LABA+LAMA, LAMA+LABA+ICS) is withheld/discontinued if a patient is receiving Ipratropium Nebules.

*Strengths of LAMA’s are expressed as base drug delivered; please see product information for further details.

MRC Breathlessness Scale:

Table 2.5. Modified MRC dyspnea scale
PLEASE TICK IN THE BOX THAT APPLIES TO YOU
(ONE BOX ONLY) (Grades 0–4)

mMRC Grade 0. I only get breathless with strenuous exercise.

mMRC Grade 1. I get short of breath when hurrying on the level or walking up a slight hill.

mMRC Grade 2. I walk slower than people of the same age on the level because of breathlessness, or I have to stop for breath when walking on my own pace on the level.

mMRC Grade 3. I stop for breath after walking about 100 meters or after a few minutes on the level.

mMRC Grade 4. I am too breathless to leave the house or I am breathless when dressing or undressing.

Self-Management Plan for COPD

This is your personal management plan. Bring it with you every time you see a nurse or doctor about your COPD.

The aim of this plan is to help you have better control of your chronic obstructive pulmonary disease (COPD). It will enable you to monitor your symptoms and to know what to do if you have an exacerbation. An exacerbation is a rapid and sustained worsening of your symptoms that may warrant a change to your regular treatment.

This plan includes sections for recording medication, monitoring symptoms and treating exacerbations.

Name: ____________________________________________________________

Date of birth: ________________ CHI: ______________________

Diagnosis/diagnoses: _____________________________________________

GP practice contact number (Mon to Fri, 8am to 6pm)
_______________________________________________________________

Oxygen saturation level
Normal oxygen saturation is 92% or above (note in some COPD patients your baseline oxygen saturation could be 88-92%. Please check with your clinician).

Your usual level is_________%

How do I keep well...
- Take daily exercise
- Eat a good balanced diet
- Drink plenty of liquids
- Do not smoke, and avoid smoky environments
- Plan ahead and have things to look forward to
- Always have enough medications. Never run out
- Take all medication regularly as prescribed whether you think they help at the time or not
- Make sure you get your annual “flu” vaccination.

If you have an oxygen monitor at home, know your baseline level from your clinician and check you oxygen level only after 10-15 minutes of resting after any exertion.
Your COPD may be GETTING WORSE if you have any of the following symptoms...

- More breathless than usual
- An increase in the amount or change in colour of your sputum
- A new or increased cough
- New or increased ankle swelling
- More frequent use of reliever medication
- Less able to do your normal activities or they are taking longer because of shortness of breath.

What action to take if your COPD symptoms are getting worse:

- Increase reliever medication
- Balance activity with plenty of rest
- Eat little and often
- Drink plenty of fluids.

What to do if your COPD symptoms are getting worse:

Continue to monitor your symptoms closely.

- If your symptoms improve within two days, continue your usual medication
- If they are no better or getting worse, continue with the increased dose of reliever medication (see page 4).

Standby exacerbation medication (see also page 5)

Steroids (prednisolone)
If you have two or more signs then start taking prednisolone.

Dose of prednisolone - 40mg once a day for 5 days

Antibiotics
If one of these signs is a change in the colour of your sputum also start an antibiotic.

What to do if you have an exacerbation of your COPD:

☐ Contact your GP or your practice nurse
☐ Contact the community/nurse respiratory service
☐ Start taking your standby supply of steroids and/or antibiotics
☐ Other __________________________

Preparation: _________________________________

Dose: _______________________________________

If you experience an exacerbation of COPD, and start prednisolone and/or antibiotics, ALWAYS advise your GP or practice nurse as soon as possible.
EMERGENCY symptoms of COPD

- Extremely short of breath with no relief from inhalers
- Chest pain
- High fever
- Feeling of agitation, drowsiness, panic or confusion.

Contact your GP surgery or the community respiratory team (if you are known to them) immediately or, outwith surgery hours phone NHS 24 on 111. In case of extreme emergency, dial 999 for an ambulance.

Have you used your standby exacerbation medication?

Remember:
- Contact your GP, or Community/Nurse Respiratory Service (delete as appropriate) if you do not start to feel better after three days of treatment
- Contact your GP, or Community/Nurse Respiratory Service (delete as appropriate) if you take more than one course of “standby” steroids and antibiotics in one month.

An exacerbation diary
